Abstract

We analyze the $1 + 1$ dimensional Nambu-Jona-Lasinio model non-perturbatively. In addition to its simple ground state saddle points, the effective action of this model has a rich collection of non-trivial saddle points in which the composite fields $\sigma(x) = \langle \bar{\psi}\psi \rangle$ and $\pi(x) = \langle \bar{\psi}i\gamma_5\psi \rangle$ form static space dependent configurations because of non-trivial dynamics. These configurations may be viewed as one dimensional chiral bags that trap the original fermions (“quarks”) into stable extended entities (“hadrons”). We provide explicit expressions for the profiles of these objects and calculate their masses. Our analysis of these saddle points is based on an explicit representation we find for the diagonal resolvent of the Dirac operator in a $\{\sigma(x), \pi(x)\}$ background which produces a prescribed number of bound states. We analyse in detail the cases of a single as well as two bound states. We find that bags that trap N fermions are the most stable ones, because they release all the fermion rest mass as binding energy and become massless. Our explicit construction of the diagonal resolvent is based on elementary Sturm-Liouville theory and simple dimensional analysis and does not depend on the large N approximation. These facts make it, in our view, simpler and more direct than the calculations previously done by Shei, using the inverse scattering method following Dashen, Hasslacher, and Neveu. Our method of finding such non-trivial static configurations may be applied to other $1 + 1$ dimensional field theories.

1 Introduction

Over the last thirty years or so, physicists have gradually learned about the behavior of quantum field theory in the non-perturbative regime. In $1+1$ dimensional spacetime, some models are exactly soluble [1]. Another important approach involves the large N expansion [2]. In particular, in the mid-seventies Dashen, Hasslacher, and Neveu [3] used the inverse scattering method [4] to determine the spectrum of the Gross-Neveu model [5]. Recently, one of us developed an alternative method, based on the Gel'fand-Dikii equation [6], to study the same problem [7] as well as other problems [8]. As will be explained below, we feel that this method has certain advantages over the inverse scattering method.

In this paper we study the $1+1$ dimensional Nambu-Jona-Lasinio (NJL) ¹ model[9] which is a renormalisable field theory defined by the action[5]

$$S = \int d^2x \left\{ \sum_{a=1}^N \bar{\psi}_a i \not{\partial} \psi_a + \frac{g^2}{2} \left[\left(\sum_{a=1}^N \bar{\psi}_a \psi_a \right)^2 - \left(\sum_{a=1}^N \bar{\psi}_a \gamma_5 \psi_a \right)^2 \right] \right\} \quad (1.1)$$

describing N self interacting massless Dirac fermions ψ_a ($a = 1, \dots, N$). This action is invariant under $SU(N)_f \otimes U(1) \otimes U(1)_A$, namely, under

$$\begin{aligned} \psi_a &\rightarrow U_{ab} \psi_b, & U &\in SU(N)_f, \\ \psi_a &\rightarrow e^{i\alpha} \psi_a, \\ \text{and } \psi_a &\rightarrow e^{i\gamma_5 \beta} \psi_a. \end{aligned} \quad (1.2)$$

We rewrite (1.1) as

$$S = \int d^2x \left\{ \bar{\psi} \left[i \not{\partial} - (\sigma + i\pi \gamma_5) \right] \psi - \frac{1}{2g^2} (\sigma^2 + \pi^2) \right\} \quad (1.3)$$

where $\sigma(x), \pi(x)$ are the scalar and pseudoscalar auxiliary fields, respectively ², which are both of mass dimension 1. These fields are singlets under $SU(N)_f \otimes U(1)$, but

¹This model is also dubbed in the literature as the ‘‘Chiral Gross-Neveu Model’’ as well as the ‘‘Multiflavor Thirring Model’’.

²From this point to the end of this paper flavor indices are suppressed. Thus $i\bar{\psi}\not{\partial}\psi$ should be understood as $i \sum_{a=1}^N \bar{\psi}_a \not{\partial} \psi_a$. Similarly $\bar{\psi}\Gamma\psi$ stands for $\sum_{a=1}^N \bar{\psi}_a \Gamma \psi_a$, where $\Gamma = 1, \gamma_5$.

transform as a vector under the axial transformation in (1.2), namely

$$\sigma + i\gamma_5\pi \rightarrow e^{-2i\gamma_5\beta}(\sigma + i\gamma_5\pi). \quad (1.4)$$

Thus, the partition function associated with (1.3) is

$$\mathcal{Z} = \int \mathcal{D}\sigma \mathcal{D}\pi \mathcal{D}\bar{\psi} \mathcal{D}\psi \exp i \int d^2x \left\{ \bar{\psi} [i\cancel{\partial} - (\sigma + i\pi\gamma_5)] \psi - \frac{1}{2g^2} (\sigma^2 + \pi^2) \right\} \quad (1.5)$$

Integrating over the grassmannian variables leads to $\mathcal{Z} = \int \mathcal{D}\sigma \mathcal{D}\pi \exp\{iS_{eff}[\sigma, \pi]\}$ where the bare effective action is

$$S_{eff}[\sigma, \pi] = -\frac{1}{2g^2} \int d^2x (\sigma^2 + \pi^2) - iN \text{Tr} \ln [i\cancel{\partial} - (\sigma + i\pi\gamma_5)] \quad (1.6)$$

and the trace is taken over both functional and Dirac indices.

This theory has been studied in the limit $N \rightarrow \infty$ with Ng^2 held fixed[5]. In this limit (1.5) is governed by saddle points of (1.6) and the small fluctuations around them. The most general saddle point condition reads

$$\begin{aligned} \frac{\delta S_{eff}}{\delta \sigma(x, t)} &= -\frac{\sigma(x, t)}{g^2} + iN \text{tr} \left[\langle x, t | \frac{1}{i\cancel{\partial} - (\sigma + i\pi\gamma_5)} | x, t \rangle \right] = 0 \\ \frac{\delta S_{eff}}{\delta \pi(x, t)} &= -\frac{\pi(x, t)}{g^2} - N \text{tr} \left[\gamma_5 \langle x, t | \frac{1}{i\cancel{\partial} - (\sigma + i\pi\gamma_5)} | x, t \rangle \right] = 0. \end{aligned} \quad (1.7)$$

In particular, the non-perturbative vacuum of (1.1) is governed by the simplest large N saddle points of the path integral associated with it, where the composite scalar operator $\bar{\psi}\psi$ and the pseudoscalar operator $i\bar{\psi}\gamma_5\psi$ develop space time independent expectation values.

These saddle points are extrema of the effective potential V_{eff} associated with (1.3), namely, the value of $-S_{eff}$ for space-time independent σ, π configurations per unit time per unit length. The effective potential V_{eff} depends only on the combination $\rho^2 = \sigma^2 + \pi^2$ as a result of chiral symmetry. V_{eff} has a minimum as a function of ρ at $\rho = m \neq 0$ that is fixed by the (bare) gap equation[5]

$$-m + iNg^2 \text{tr} \int \frac{d^2k}{(2\pi)^2} \frac{1}{\not{k} - m} = 0 \quad (1.8)$$

which yields the dynamical mass

$$m = \Lambda e^{-\frac{\pi}{Ng^2(\Lambda)}}. \quad (1.9)$$

Here Λ is an ultraviolet cutoff. The mass m must be a renormalisation group invariant. Thus, the model is asymptotically free. We can get rid of the cutoff at the price of introducing an arbitrary renormalisation scale μ . The renormalised coupling $g_R(\mu)$ and the cut-off dependent bare coupling are then related through $\Lambda e^{-\frac{\pi}{Ng^2(\Lambda)}} = \mu e^{1-\frac{\pi}{Ng_R^2(\mu)}}$ in a convention where $Ng_R^2(m) = \frac{1}{\pi}$. Trading the dimensionless coupling g_R^2 for the dynamical mass scale m represents the well known phenomenon of dimensional transmutation.

The vacuum manifold of (1.3) is therefore a circle $\rho = m$ in the σ, π plane, and the equivalent vacua are parametrised by the chiral angle $\theta = \arctan \frac{\pi}{\sigma}$. Therefore, small fluctuations of the Dirac fields around the vacuum manifold develop dynamical³ chiral mass $m \exp(i\theta\gamma_5)$.

Note in passing that the massless fluctuations of θ along the vacuum manifold decouple from the spectrum [10] so that the axial $U(1)$ symmetry does not break dynamically in this two dimensional model [11].

Non-trivial excitations of the vacuum, on the other hand, are described semiclassically by large N saddle points of the path integral over (1.1) at which σ and π develop space-time dependent expectation values [12, 13]. These expectation values are the space-time dependent solution of (1.7). Saddle points of this type are important also in discussing the large order behavior [14, 15] of the $\frac{1}{N}$ expansion of the path integral over (1.1).

Shei [16] has studied the saddle points of the NJL model by applying the inverse scattering method following Dashen et al. [3]. These saddle points describe sectors of (1.1) that include scattering states of the (dynamically massive) fermions in (1.1), as well as a rich collection of bound states thereof.

These bound states result from the strong infrared interactions, which polarise the

³Note that the axial $U(1)$ symmetry in (1.2) protects the fermions from developing a mass term to any order in perturbation theory.

vacuum inhomogeneously, causing the composite scalar $\bar{\psi}\psi$ and pseudoscalar $i\bar{\psi}\gamma_5\psi$ fields to form finite action space-time dependent condensates. These condensates are stable because of the binding energy released by the trapped fermions and therefore cannot form without such binding. This description agrees with the general physical picture drawn in [17]. We may regard these condensates as one dimensional chiral bags [18, 19] that trap the original fermions (“quarks”) into stable finite action extended entities (“hadrons”).

In this paper we develop further the method of [7, 8], applying it to the NJL model (1.1) as an alternative to the inverse scattering investigations in [16]. We focus on static extended configurations providing explicit expressions for the profiles of these objects and calculate their masses. Our analysis of these static saddle points is based on an explicit representation we find for the diagonal resolvent of the Dirac operator in a $\sigma(x), \pi(x)$ background which produces a prescribed number of bound states. This explicit construction of the diagonal resolvent can actually be carried out for finite N . It is based on elementary Sturm-Liouville theory as well as on simple dimensional analysis. All our manipulations involve the space dependent scalar and pseudoscalar condensates directly. In our view, these facts make the method presented here simpler than inverse scattering calculations previously employed in this problem because we do not need to work with the scattering data and the so called trace identities that relate them to the space dependent condensates. Our method of finding such non-trivial static configurations may be applied to other two dimensional field theories.

It is worth mentioning at this point that the NJL model (1.1) is completely integrable for any number of flavors⁴ N . Its spectrum and completely factorised S matrix were determined in a series of papers [20] by a Bethe ansatz diagonalisation of the Hamiltonian for any number N of flavors. The large N spectrum obtained here as well as in [16] is consistent with the exact solution of [20]. Note, however, that the large N analysis in this paper concerns only dynamics of the interactions between

⁴For $N = 1$ a simple Fierz transformation shows that (1.1) is simply the massless Thirring model, which is a conformal quantum field theory having no mass gap. A mass gap appears dynamically only for $N \geq 2$.

fermions and extended objects. We do not address issues like scattering of one extended object on another, which is discussed in the exact analysis of [20]. Consistency of our approximate large N results and the exact results of [20] reassures us of the validity of our calculations.

Rather than treating non-trivial excitations as abstract vectors in Hilbert space, which is inevitable in [20], our analysis draws almost a “mechanical” picture of how “hadrons” arise in the NJL model. This description of “hadron” formation as a result of inhomogeneous polarisations of the vacuum due to strong infrared interactions may have some restricted similarity to dynamics of QCD in the real world. Furthermore, our resolvent method is potentially applicable for non-integrable models in $1+1$ dimensions. In contrast, Bethe ansatz and factorisable S matrix techniques are limited in principle to $1+1$ dimensions because of the Coleman-Mandula theorem[21], whereas large N saddle point techniques may provide powerful tools in analysis of more realistic higher dimensional field theories[22].

If we set $\pi(x)$ in (1.3) to be identically zero, we recover the Gross-Neveu model, defined by

$$S_{GN} = \int d^2x \left\{ \bar{\psi} [i\!\not{\partial} - \sigma] \psi - \frac{\sigma^2}{2g^2} \right\}. \quad (1.10)$$

In spite of their similarities, these two field theories are quite different, as is well-known from the field theoretic literature of the seventies. The crucial difference is that the Gross-Neveu model possesses a discrete symmetry, $\sigma \rightarrow -\sigma$, rather than the continuous symmetry (1.2) in the NJL model studied here. This discrete symmetry is dynamically broken by the non-perturbative vacuum, and thus there is a kink solution [23, 3, 7], the so-called Callan-Coleman-Gross-Zee (CCGZ) kink $\sigma(x) = m \tanh(mx)$, interpolating between $\pm m$ at $x = \pm\infty$ respectively. Therefore, topology insures the stability of these kinks.

In contrast, the NJL model, with its continuous symmetry, does not have a topologically stable soliton solution. The solitons arising in the NJL model and studied in this paper can only be stabilised by binding fermions. To stress this observation further, we note that the spectrum of the Dirac operator of the Gross-Neveu model

in the background of a CCGZ kink has a single bound state at zero energy, and therefore no binding energy is released when they trap (any number of) fermions. The stability of the kinks in the Gross-Neveu model is guaranteed by topology already. In contrast, the stability of the extended objects studied here is not due to topology, but to dynamics.

This paper is organised as follows: In Section 2 we prove that the static condensates $\sigma(x)$ and $\pi(x)$ in (1.3) must be such that the resulting Dirac operator is reflectionless. Our proof of this strong restriction on the Dirac operator involves basic field theoretic arguments and has nothing to do with the large N approximation. We next show in Section 3 that if we fix in advance the number of bound states in the spectrum of the reflectionless Dirac operator, then simple dimensional analysis determines the diagonal resolvent of this operator explicitly in terms of the background fields and their derivatives. We then construct the resolvent assuming the background fields support a single bound state in Subsection 4.1. We are able to determine the profile of the background fields up to a finite number of parameters: the relative chiral rotation of the two vacua at the two ends of the one dimensional space and the bound state energies. In Subsection 4.2 we provide partial analysis of the case of two bound states. We stress again that our construction of these background fields has nothing to do with the large N approximation.

In order to determine these parameters we have to impose the saddle point condition. We do so in Sections 5.1 and 5.2. The relative chiral rotation of the asymptotic vacua is proportional to the number of fermions trapped in the bound states, in accordance with [24].

Some technical details are left to two appendices. In Appendix A we derive the spatial asymptotic behavior of the static Dirac operator Green's function. In order to make our paper self contained we derive the Gel'fand-Dikii equation in Appendix B.

2 Absence of Reflections in the Dirac Operator With Static Background Fields

As was explained in the introduction, we are interested in static space dependent solutions of the extremum condition on S_{eff} . To this end we need to invert the Dirac operator

$$D \equiv \left[i\not{\partial} - (\sigma(x) + i\pi(x)\gamma_5) \right] \quad (2.1)$$

in a given background of static field configurations $\sigma(x)$ and $\pi(x)$. In particular, we have to find the diagonal resolvent of (2.1) in that background. The extremum condition on S_{eff} relates this resolvent, which in principle is a complicated and generally unknown functional of $\sigma(x)$, $\pi(x)$ and of their derivatives, to $\sigma(x)$ and $\pi(x)$ themselves. This complicated relation is the source of all difficulties that arise in any attempt to solve the model under consideration. It turns out, however, that basic field theoretic considerations, that are unrelated to the extremum condition, imply that (2.1) must be reflectionless. This spectral property of (2.1) sets rather powerful restrictions on the static background fields $\sigma(x)$ and $\pi(x)$ which are allowed dynamically. In the next section we show how this special property of (2.1) allows us to write explicit expressions for the resolvent in some restrictive cases, that are interesting enough from a physical point of view.

Inverting (2.1) has nothing to do with the large N approximation, and consequently our results in this section are valid for any value of N .

Here $\sigma(x)$ and $\pi(x)$ are our static background field configurations, for which we assume asymptotic behavior dictated by simple physical considerations. The overall energy deposited in any relevant static σ, π configuration must be finite. Therefore these fields must approach constant vacuum asymptotic values, while their derivatives vanish asymptotically. Then the axial $U(1)$ symmetry implies that $\sigma^2 + \pi^2 \xrightarrow{x \rightarrow \pm\infty} m^2$, where m is the dynamically generated mass, and therefore we arrive at the asymptotic

boundary conditions for σ and π ,

$$\begin{aligned} \sigma &\xrightarrow{x \rightarrow \pm\infty} m \cos \theta_{\pm} \quad , \quad \sigma' \xrightarrow{x \rightarrow \pm\infty} 0 \\ \pi &\xrightarrow{x \rightarrow \pm\infty} m \sin \theta_{\pm} \quad , \quad \pi' \xrightarrow{x \rightarrow \pm\infty} 0 \end{aligned} \quad (2.2)$$

where $\theta_{\pm}$ are the asymptotic chiral alignment angles. Only the difference $\theta_+ - \theta_-$ is meaningful, of course, and henceforth we use the axial symmetry to set $\theta_- = 0$, such that $\sigma(-\infty) = m$ and $\pi(-\infty) = 0$. We also omit the subscript from θ_+ and denote it simply by θ from now on. It is in the background of such fields that we wish to invert (2.1).

In this paper we use the Majorana representation $\gamma^0 = \sigma_2$, $\gamma^1 = i\sigma_3$ and $\gamma^5 = -\gamma^0\gamma^1 = \sigma_1$ for γ matrices. In this representation (2.1) becomes

$$D = \begin{pmatrix} -\partial_x - \sigma & -i\omega - i\pi \\ i\omega - i\pi & \partial_x - \sigma \end{pmatrix}. \quad (2.3)$$

Inverting (2.3) is achieved by solving

$$\begin{pmatrix} -\partial_x - \sigma(x) & -i\omega - i\pi(x) \\ i\omega - i\pi(x) & \partial_x - \sigma(x) \end{pmatrix} \cdot \begin{pmatrix} a(x, y) & b(x, y) \\ c(x, y) & d(x, y) \end{pmatrix} = -i\mathbf{1}\delta(x - y) \quad (2.4)$$

for the Green's function of (2.3) in a given background $\sigma(x), \pi(x)$. By dimensional analysis, we see that the quantities a, b, c and d are dimensionless.

The diagonal elements $a(x, y)$, $d(x, y)$ in (2.4) may be expressed in term of the off-diagonal elements as

$$a(x, y) = \frac{i [\partial_x - \sigma(x)] c(x, y)}{\omega - \pi(x)}, \quad d(x, y) = \frac{i [\partial_x + \sigma(x)] b(x, y)}{\omega + \pi(x)} \quad (2.5)$$

which in turn satisfy the second order partial differential equations

$$\begin{aligned} -\partial_x \left[\frac{\partial_x b(x, y)}{\omega + \pi(x)} \right] + \left[\sigma(x)^2 + \pi(x)^2 - \sigma'(x) - \omega^2 + \frac{\sigma(x)\pi'(x)}{\omega + \pi(x)} \right] \frac{b(x, y)}{\omega + \pi(x)} &= \delta(x - y) \\ -\partial_x \left[\frac{\partial_x c(x, y)}{\omega - \pi(x)} \right] + \left[\sigma(x)^2 + \pi(x)^2 + \sigma'(x) - \omega^2 + \frac{\sigma(x)\pi'(x)}{\omega - \pi(x)} \right] \frac{c(x, y)}{\omega - \pi(x)} &= -\delta(x - y). \end{aligned} \quad (2.6)$$

Thus, $b(x, y)$ and $-c(x, y)$ are simply the Green's functions of the corresponding second order Sturm-Liouville operators in (2.6),

$$\begin{aligned} b(x, y) &= \frac{\theta(x-y) b_2(x) b_1(y) + \theta(y-x) b_2(y) b_1(x)}{W_b} \\ c(x, y) &= -\frac{\theta(x-y) c_2(x) c_1(y) + \theta(y-x) c_2(y) c_1(x)}{W_c}. \end{aligned} \quad (2.7)$$

Here $b_1(x)$ and $b_2(x)$ are the Jost functions of the first equation in (2.6) and

$$W_b = \frac{b_2(x) b_1'(x) - b_1(x) b_2'(x)}{\omega + \pi(x)}. \quad (2.8)$$

is their Wronskian. The latter is independent of x , since b_1 and b_2 share a common value of the spectral parameter ω^2 . Similarly, c_1, c_2 are the Jost functions of the second equation in (2.6) and W_c is their Wronskian. We leave the precise definition of these Jost functions in terms of their spatial asymptotic behavior to Appendix A, where we also derive the spatial asymptotic behavior of the static Dirac operator Green's function. Substituting (2.7) into (2.5) we obtain the appropriate expressions for $a(x, y)$ and $d(x, y)$, which we do not write explicitly.⁵

We define the diagonal resolvent $\langle x | iD^{-1} | x \rangle$ symmetrically as

$$\begin{aligned} \langle x | -iD^{-1} | x \rangle &\equiv \begin{pmatrix} A(x) & B(x) \\ C(x) & D(x) \end{pmatrix} \\ &= \frac{1}{2} \lim_{\epsilon \rightarrow 0^+} \begin{pmatrix} a(x, y) + a(y, x) & b(x, y) + b(y, x) \\ c(x, y) + c(y, x) & d(x, y) + d(y, x) \end{pmatrix}_{y=x+\epsilon}. \end{aligned} \quad (2.9)$$

Here $A(x)$ through $D(x)$ stand for the entries of the diagonal resolvent, which following (2.5) and (2.7) have the compact representation⁶

$$B(x) = \frac{b_1(x) b_2(x)}{W_b}, \quad D(x) = \frac{i [\partial_x + 2\sigma(x)] B(x)}{2(\omega + \pi(x))},$$

⁵It is useful however to note, that despite the ∂_x operation in (2.5), neither $a(x, y)$ nor $d(x, y)$ contain pieces proportional to $\delta(x - y)$. Such pieces cancel one another due to the symmetry of (2.7) under $x \leftrightarrow y$.

⁶ A, B, C and D are obviously functions of ω as well. For notational simplicity we suppress their explicit ω dependence.

$$C(x) = -\frac{c_1(x)c_2(x)}{W_c} \quad , \quad A(x) = \frac{i}{2} \frac{[\partial_x - 2\sigma(x)] C(x)}{\omega - \pi(x)}. \quad (2.10)$$

A simplifying observation is that the two linear operators on the left hand side of the equations (2.6) transform one into the other under a simultaneous sign flip⁷ of $\sigma(x)$ and $\pi(x)$. Therefore $c(\sigma, \pi) = -b(-\sigma, -\pi)$, and in particular

$$C(\sigma, \pi) = -B(-\sigma, -\pi), \quad (2.11)$$

and thus all four entries of the diagonal resolvent (2.9) may be expressed in terms of $B(x)$.

The spatial asymptotic behavior of (2.9) is derived in Appendix A and given by (A.6). A more compact form of that result is

$$\begin{aligned} \langle x | -iD^{-1} | x \rangle \xrightarrow{x \rightarrow \pm\infty} & \frac{1 + R(k) e^{2ik|x|}}{2k} \left[i\gamma_5 \pi(x) - \sigma(x) - \gamma^0 \omega \right] \\ & + \frac{R(k) e^{2ik|x|}}{2} \gamma^1 \operatorname{sgn} x \end{aligned} \quad (2.12)$$

where $k = \sqrt{\omega^2 - m^2}$ and $R(k)$ is the reflection coefficient of the first equation in (2.6).

Note that for $\omega^2 > m^2$, *i.e.*, in the continuum part of the spectrum of (2.3), the piece of the resolvent (2.12) that is proportional to $R(k)$ oscillates persistently as a function of x . This observation has a far reaching result that we now derive. Consider the expectation value of fermionic vector current operator j^μ in the static $\sigma(x)$, $\pi(x)$ background⁸

$$\langle \sigma(x), \pi(x) | j^\mu | \sigma(x), \pi(x) \rangle = - \int \frac{d\omega}{2\pi} \operatorname{tr} \left[\gamma^\mu \begin{pmatrix} A(x) & B(x) \\ C(x) & D(x) \end{pmatrix} \right]. \quad (2.13)$$

⁷This is merely a reflection of the fact that coupling the fermions to $\pi\gamma_5$ does not respect charge conjugation invariance.

⁸In the following it is enough to discuss only the vector current, because the axial current $j_5^\mu = \epsilon^{\mu\nu} j_\nu$.

Therefore, we find from (2.12) that the asymptotic behavior of the current matrix elements is

$$\langle \sigma(x), \pi(x) | j^0 | \sigma(x), \pi(x) \rangle \xrightarrow{x \rightarrow \pm\infty} 0$$

and

$$\langle \sigma(x), \pi(x) | j^1 | \sigma(x), \pi(x) \rangle \xrightarrow{x \rightarrow \pm\infty} - \int \frac{d\omega}{2\pi} R(k) e^{2ik|x|} \quad (2.14)$$

where we used the fact that $\int \frac{d\omega}{2\pi} \frac{\omega}{k} f(k) = 0$ because $k(\omega)$ is an even function of ω .

Thus, an arbitrary static background $\sigma(x), \pi(x)$ induces fermion currents that do not decay as $x \rightarrow \pm\infty$, unless $R(k) \equiv 0$. Clearly, we cannot have such currents in our static problem and we conclude that as far as the field theory (1.3) is concerned, the fields $\sigma(x), \pi(x)$ must be such that the Sturm-Liouville operators in (2.6) and therefore the Dirac operator (2.3) are reflectionless.

The absence of reflections emerges here from basic principles of field theory, and not merely as a large N saddle point condition, as in [3, 16]. Indeed, reflectionlessness of (2.3) must hold whatever the value of N is. Therefore, the fact that reflectionlessness of (2.3) appeared in [3, 16] as a saddle point condition in the inverse scattering formalism simply indicates consistency of the large N approximation in analysing space dependent condensations $\sigma(x), \pi(x)$. The absence of reflections also restores asymptotic translational invariance. What we mean by this statement is that if $R(k) \equiv 0$ then (2.12) is simply the result of inverting (2.3) in Fourier space with constant asymptotic background (2.2), namely,

$$\langle x | -iD^{-1} | x \rangle = \frac{1}{2\sqrt{m^2 - \omega^2}} \begin{pmatrix} im\cos\theta & \omega + m\sin\theta \\ -\omega + m\sin\theta & im\cos\theta \end{pmatrix} \quad (2.15)$$

which therefore yields the asymptotic behavior of (2.9) for properly chosen chiral alignment angles. Note that in the absence of reflections, (2.12) attains its asymptotic value (2.15) by simply following the asymptotic behavior of $\sigma(x)$ and of $\pi(x)$, which are the exclusive sources of any asymptotic x dependence of the resolvent. This

expression (2.15) has cuts in the complex ω plane stemming from scattering states of fermions of mass m . These cuts must obviously persist in A, B, C and D away from the asymptotic region, and we make use of this fact in the next section. We used the asymptotic matrix elements (2.13) of the vector current operator in the background of static $\sigma(x)$, $\pi(x)$ to establish the absence of reflections in the static Dirac operator. We can now make use of this result to examine its general dynamical implications on matrix elements of other interesting operators, namely, the scalar $\bar{\psi}\psi$ and pseudoscalar $\bar{\psi}i\gamma_5\psi$ density operators. Their matrix elements in the background of $\sigma(x)$, $\pi(x)$ are

$$\langle \sigma(x), \pi(x) | \bar{\psi}\psi | \sigma(x), \pi(x) \rangle = N \int \frac{d\omega}{2\pi} \text{tr} \langle x | iD^{-1} | x \rangle$$

and

$$\langle \sigma(x), \pi(x) | \bar{\psi}i\gamma_5\psi | \sigma(x), \pi(x) \rangle = N \int \frac{d\omega}{2\pi} \text{tr} \left[i\gamma_5 \langle x | iD^{-1} | x \rangle \right]. \quad (2.16)$$

Therefore, from (2.12) their asymptotic behavior is simply

$$\langle \sigma(x), \pi(x) | \bar{\psi}\psi | \sigma(x), \pi(x) \rangle \xrightarrow{x \rightarrow \pm\infty} N\sigma(x) \int \frac{d\omega}{2\pi} \frac{1 + R(k) e^{2ik|x|}}{k}$$

and

$$\langle \sigma(x), \pi(x) | \bar{\psi}i\gamma_5\psi | \sigma(x), N\pi(x) \rangle \xrightarrow{x \rightarrow \pm\infty} \pi(x) \int \frac{d\omega}{2\pi} \frac{1 + R(k) e^{2ik|x|}}{k}. \quad (2.17)$$

Clearly, in the absence of reflections, the asymptotic x dependence of these matrix elements follows the profiles of $\sigma(x)$ and $\pi(x)$, respectively. Otherwise, if $R(k) \neq 0$, these matrix elements will have further powerlike decay in x superimposed on these profiles, which is not related directly to the typical length scales appearing in $\sigma(x)$ and in $\pi(x)$. We close this section by investigating implications of (2.17) for extremal background configurations. For such configurations the matrix element of the scalar density is equal to $\sigma(x)/g^2$ and that of the pseudoscalar density is equal to $\pi(x)/g^2$. Such background fields must obviously correspond to a reflectionless Dirac operator, but let us for the moment entertain ourselves with the assumption that $R(k)$ in (2.17) is arbitrary and see how the absence of reflections appears as a saddle point condition. Thus, for extremal configurations, as $x \rightarrow \pm\infty$, $\sigma(x)$ cancels off both sides of the first

equation in (2.17) and $\pi(x)$ cancels off both sides of the other equation. This leaves us with a common dispersion integral

$$\frac{1}{Ng^2} = \int \frac{d\omega}{2\pi} \frac{1 + R(k) e^{2ik|x|}}{k}.$$

It turns out (see (5.21 below) that the integral over the first x independent term on the right hand side cancels precisely the constant term on the left hand side. This is simply a reformulation of (1.8) in Minkowski space. Therefore, the remaining x dependent integral must vanish for any (large) $|x|$. It follows then, that $R(k)$ must vanish. Thus absence of reflections appears here as a saddle point requirement, in a rather simple elegant manner, without ever invoking the inverse scattering transform. The whole purpose of this section is to prove that one cannot consider static reflectionful backgrounds to begin with, and thus the emergence of absence of reflections as a saddle point condition is simply a successful consistency check for the validity of the large N approximation applied to space dependent condensates.

3 The Diagonal Resolvent for a Fixed Number of Bound States

The requirement that the static Dirac operator (2.3) be reflectionless is by itself quite restrictive, since most $\sigma(x), \pi(x)$ configurations will not lead to a reflectionless static Dirac operator. Construction of explicit expressions for the resolvent in terms of $\sigma(x), \pi(x)$ and their derivatives is a formidable task even under such severe restrictions on these fields. We now show how to accomplish such a construction at the price of posing further restrictions on $\sigma(x)$ and $\pi(x)$ in function space. However, even under these further restrictions the results we obtain are still quite interesting from a physical point of view.

In the following we concentrate on the $B(x)$ component of (2.9). The other entries in (2.9) may be deduced from $B(x)$ through (2.10) and (2.11).

Our starting point here is the observation that one can derive from the representation of $B(x)$ in (2.10) a functional identity in the form of a differential equation relating $B(x)$ to $\sigma(x)$ and $\pi(x)$ without ever knowing the explicit form of the Jost functions $b_1(x)$ and $b_2(x)$. We leave the details of derivation to Appendix B, where we show that the identity mentioned above is

$$\begin{aligned} & \partial_x \left\{ \frac{1}{\omega + \pi(x)} \partial_x \left[\frac{\partial_x B(x)}{\omega + \pi(x)} \right] \right\} \\ & - \frac{4}{\omega + \pi(x)} \left\{ \partial_x \left[\frac{B(x)}{\omega + \pi(x)} \right] \right\} \left[\sigma(x)^2 + \pi(x)^2 - \sigma'(x) - \omega^2 + \frac{\sigma(x)\pi'(x)}{\omega + \pi(x)} \right] \\ & - \frac{2B(x)}{[\omega + \pi(x)]^2} \partial_x \left[\sigma(x)^2 + \pi(x)^2 - \sigma'(x) + \frac{\sigma(x)\pi'(x)}{\omega + \pi(x)} \right] \equiv 0 \end{aligned} \quad (3.1)$$

with a similar expression for $C(x)$ in which $\sigma \rightarrow -\sigma$ $\pi \rightarrow -\pi$ that we do not write down explicitly.

Here we denote derivatives with respect to x either by primes or by partial derivatives. This equation is a linear form of what is referred to in the mathematical

literature as the “Gel’fand-Dikii” identity[6]. This identity merely reflects the fact that $B(x)$ is the diagonal resolvent of the Strum-Liouville operator discussed above and sets no restrictions on $\sigma(x)$ and $\pi(x)$.

If we were able to solve (3.1) for $B(x)$ in a closed form for any static configuration of $\sigma(x), \pi(x)$, we would then be able to express $\langle x | iD^{-1} | x \rangle$ in terms of the latter fields and their derivatives, and therefore to integrate (1.7) back to find an expression for the effective action (1.6) explicitly in terms of $\sigma(x)$ and $\pi(x)$. Invoking at that point Lorentz invariance of (1.6) we would then actually be able to write down the full effective action for space-time dependent σ and π . Note moreover that in principle such a procedure would yield an exact expression for the effective action, regardless of what N is.

Unfortunately, deriving such an expression for $B(x)$ is a difficult task, and thus we set ourselves a simpler goal in this paper, by determining the desired expression for $B(x)$ with $\sigma(x), \pi(x)$ restricted to a specific sectors in the space of all possible static configurations. To specify these sectors consider the Dirac equation associated with (2.1), $D\psi = 0$. For a given configuration of $\sigma(x), \pi(x)$ (such that D is reflectionless), this equation has n bound states at energies $\omega_1, \dots, \omega_n$ as well as scattering states. A given sector is then defined by specifying the number of bound states the Dirac equation has.⁹

As we saw above, $B(x)$ must have a cut in the ω plane with branch points at $\omega = \pm m$. If in addition to scattering states $\sigma(x), \pi(x)$ support n bound states at energies $\omega_1, \dots, \omega_n$ (which must all lie in the real interval $-m < \omega < m$)¹⁰ then the corresponding B must contain a simple pole for each of these bound states. Therefore,

⁹The effect of scattering states on $B(x)$ is rigidly fixed by spatial asymptotics, as (2.15) indicates, so only bound states are used to specify such a sector.

¹⁰The Gross-Neveu model[5, 3, 7] is a theory of Majorana (real) fermions. Therefore its spectrum is invariant under charge conjugation, i.e., it is symmetric under $\omega \rightarrow -\omega$. Thus in that case the bound states are paired symmetrically around $\omega = 0$ and $B(x)$ is really a function of ω^2 . The chiral NJL model on the other hand is a theory of Dirac (complex) fermions, charge conjugation symmetry of the spectrum is broken by the π field and bound states are not paired.

$B(x)$ must contain the purely ω dependent factor

$$\frac{1}{\sqrt{m^2 - \omega^2} \prod_{k=1}^n (\omega - \omega_k)} \quad (3.2)$$

of mass dimension $-n - 1$. Any other singularity $B(x)$ may have in the complex ω plane cannot be directly related to the spectrum of the

Dirac operator, and therefore must involve x dependence as well. Based on our discussion in Appendix A, the only possible combination that mixes these variables is $\exp(i\sqrt{\omega^2 - m^2} x)$. But such a combination is ruled out as we elaborated in the previous section, by the requirement that the Dirac operator be reflectionless. The factor (3.2) then exhausts all allowed singularities of $B(x)$ in the complex ω plane. Recall further that $B(x)$ is a dimensionless quantity, and thus the negative dimension of the ω dependent factor (3.2) must be balanced by a polynomial of degree $n + 1$ in ω (with x dependent coefficients) of mass dimension $n + 1$, namely¹¹

$$B(x, \omega) = \frac{B_{n+1}(x)\omega^{n+1} + \dots + B_1(x)\omega + B_0(x)}{\sqrt{m^2 - \omega^2} \prod_{k=1}^n (\omega - \omega_k)}. \quad (3.3)$$

The mass dimension of $B_k(x)$ ($k = 0, \dots, n + 1$) is $n + 1 - k$.

The main point here is that simple dimensional analysis in conjunction with the prescribed analytic properties of $B(x)$ fix its ω dependence completely, up to $n + 1$ unknown bound state energies, and $n + 2$ unknown functions of $\sigma(x), \pi(x)$ and their derivatives. These functions are by no means arbitrary. They have to be such that (3.3) and the resulting expression for $C(x)$ are indeed the resolvents of the appropriate Sturm-Liouville operators. These expressions for $B(x)$ and $C(x)$ must be therefore subjected to the Gel'fand-Dikii identities (3.1) and the corresponding identity for $C(x)$.

Substituting $B(x)$ into (3.1) we obtain an equation of the form

$$Q_{n+5}^{(B)}(\omega, x) / [\omega + \pi(x)]^4 \equiv 0, \quad (3.4)$$

¹¹One may argue that Eq. (3.3) should be further multiplied by a dimensionless bounded function $f(\frac{\omega}{m})$. However such a function must be entire, otherwise it will change the prescribed singularity properties of $B(x)$, but the only bounded entire functions are constant.

where $Q_{n+5}^{(B)}(\omega, x)$ is a polynomial of degree $n + 5$ in ω with x dependent coefficients that are linear combinations of the functions $B_k(x)$ and their first three derivatives.

Note that because of the linearity and homogeneity of (3.1), the purely ω dependent denominator of (3.3) with its explicit dependence on the bound state energies drops out from (3.4). This is actually the main advantage¹² of working with the linear form of the Gel'fand-Dikii identity rather than with its non-linear form (B.10)[7].

Setting to zero each of the x dependent coefficients in $Q_{n+5}^{(B)}$ we obtain an overdetermined system of $n + 6$ linear differential equations in the $n + 2$ functions $B_k(x)$. Using $n + 2$ of the equations we fix all the functions $B_k(x)$ in terms of $\sigma(x)$, $\pi(x)$ and their derivatives, up to $n + 2$ integration constants b_k . These integration constants are completely determined once we enforce on the resulting expression for $B(x)$ the asymptotic behavior (2.2) and (2.15). The integration constants b_k turn out to be polynomials in m^2 and the bound state energies ω_k .

At this stage we are left, independently of n , with four non-linear differential equations in $\sigma(x)$ and $\pi(x)$ ¹³. A similar analysis applies for $C(x)$, leading to an equation of the form $Q_{n+5}^{(C)}(\omega, x) \equiv 0$, where following (2.11) $Q_{n+5}^{(C)}(\omega, \sigma(x), \pi(x)) = -Q_{n+5}^{(B)}(\omega, -\sigma(x), -\pi(x))$. Setting the first $n + 2$ coefficients in $Q_{n+5}^{(C)}(\omega, x)$ to zero we verify that $C(x)$ is related to $B(x)$ as in (2.11), but that the remaining four equations for $\sigma(x)$ and $\pi(x)$ are different from their counterparts associated with $B(x)$ as the explicit relation between $Q_{n+5}^{(C)}$ and $Q_{n+5}^{(B)}$ suggests. We are thus left with an overdetermined set of eight non-linear differential equations for the two functions $\sigma(x)$ and $\pi(x)$. Observing that $Q_{n+5}^{(C)} \pm Q_{n+5}^{(B)}$ is odd (even) in σ and π , we note that these eight equations are equivalent to breaking each of the four remaining equations associated with $B(x)$ into a part even in σ and π and a part odd in σ and π and setting each of these parts to zero separately.

Mathematical consistency of our analysis requires that the six most complicated

¹²The non-linear version of the Gel'fand-Dikii identity (B.8) (or (B.10)) contains further information about the normalisation of $B(x)$, but the latter may be readily determined from the asymptotic behavior (2.15) of $B(x)$.

¹³Coefficients of the various terms in these equations are also polynomials in m^2 and the bound state energies ω_k .

equations of the total eight be redundant relative to the remaining two equations, because we have only two unknown functions, $\sigma(x)$ and $\pi(x)$. This requirement must be fulfilled, because otherwise we are compelled to deduce that there can be no $\sigma(x)$ and $\pi(x)$ configurations for which the Dirac equation $D\psi = 0$ has precisely n bound states, with $n = 0, 1, 2, \dots$, which is presumably an erroneous conclusion.

Therefore $\sigma(x)$ and $\pi(x)$ are uniquely determined from the two independent equations given the asymptotic boundary conditions (2.2) they satisfy. This leaves only the bound state energies undetermined, but the latter cannot be determined by the resolvent identity, which does not really care what their values are. These energies are determined by imposing the saddle point conditions (1.7), i.e., by dynamical aspects of the model under investigation.

In the preceding paragraphs we laid down the mathematical aspects of our analysis. We now add to these a symmetry argument which will simplify our solution of the differential equations for $\sigma(x)$ and $\pi(x)$ a great deal. The two non-redundant coupled differential equations for $\sigma(x)$ and $\pi(x)$ allow us to eliminate one of these functions in terms of the other. We choose to eliminate¹⁴ $\pi(x)$ in terms of $\sigma(x)$,

$$\pi_\alpha(x) = G_\alpha[\sigma_\alpha(x)] \quad (3.5)$$

where α is a global chiral alignment angle. This relation is clearly covariant under axial rotations $\alpha \rightarrow \alpha + \Delta\alpha$, because $\sigma(x)$ and $\pi(x)$ transform as the two components of a vector under $U(1)_A$ as (1.4) shows. We expect (3.5) to be a linear relation. Imposing the boundary conditions (2.2) we have

$$\pi(x) = -[\sigma(x) - m] \cot \frac{\theta}{2}. \quad (3.6)$$

In this way we reduce the problem into finding the single function $\sigma(x)$. The condition (3.6) is an external supplement to the coupled differential equations for $\sigma(x)$ and $\pi(x)$ stemming from the Gel'fand-Dikii equation. We thus have to make sure that the resulting solution for $\sigma(x)$ and (3.6) are indeed solutions of these coupled differential equations.

¹⁴We prefer to eliminate $\pi(x)$ in terms of $\sigma(x)$ because the latter never vanishes identically.

We now provide the details of such calculations in the case of a single bound state, as well as partial results concerning two bound states.

4 Extended Object Profiles

4.1 A single bound state

In this case (3.3) becomes

$$B(x) = \frac{B_2(x)\omega^2 + B_1(x)\omega + B_0(x)}{(\omega - \omega_1)\sqrt{m^2 - \omega^2}} \quad (4.1)$$

where the single bound state energy is ω_1 . Then setting to zero the coefficients of ω^6 through ω^4 in the degree six polynomial (3.4), we find

$$\begin{aligned} B_2(x) &= b_2, & B_1(x) &= b_2\pi(x) + b_1 & \text{and} \\ B_0(x) &= b_1\pi(x) + \frac{b_2}{2} [\sigma^2(x) + \pi^2(x) - \sigma'(x)] + b_0 \end{aligned} \quad (4.2)$$

where b_2, b_1 and b_0 are integration constants. We then impose the asymptotic boundary conditions

$$B(x) \xrightarrow{x \rightarrow \pm\infty} \frac{1}{2\sqrt{m^2 - \omega^2}} (\omega + m\sin\theta_{\pm})$$

to fix the latter,

$$b_2 = \frac{1}{2}, \quad b_1 = -\frac{\omega_1}{2}, \quad b_0 = -\frac{m^2}{4} \quad (4.3)$$

and therefore

$$B(x) = \frac{\omega + \pi(x)}{2\sqrt{m^2 - \omega^2}} + \frac{\sigma^2(x) + \pi^2(x) - \sigma'(x) - m^2}{4(\omega - \omega_1)\sqrt{m^2 - \omega^2}}. \quad (4.4)$$

The relation (2.11) then immediately leads to

$$C(x) = -\frac{\omega - \pi(x)}{2\sqrt{m^2 - \omega^2}} - \frac{\sigma^2(x) + \pi^2(x) + \sigma'(x) - m^2}{4(\omega - \omega_1)\sqrt{m^2 - \omega^2}}. \quad (4.5)$$

Having the coefficients of ω^6 through ω^4 in the degree six polynomial (3.4) set to zero, we are left with a cubic polynomial

$$\begin{aligned} 4\partial_x \left\{ \left[\left(m^2 - \pi^2(x) - \sigma^2(x) \right) \pi(x) - \omega_1 \sigma'(x) + \frac{1}{2} \pi''(x) \right] + \right. \\ \left. \left[\omega_1 \left(\pi^2(x) + \sigma^2(x) \right) - \sigma(x) \pi'(x) + \sigma'(x) \pi(x) \right] \right\} \omega^3 + \dots \equiv 0 \end{aligned} \quad (4.6)$$

where the $(\dots)$ stand for lower powers of ω . The cubic (4.6) has to be set to zero identically, producing eight coupled differential equations in $\sigma(x)$ and $\pi(x)$ as we discussed above. The simplest equation of these is obtained by setting to zero the part of the ω^3 coefficient in (4.6) that is even in σ and π , namely,

$$\partial_x \left[\omega_1 \left(\pi^2(x) + \sigma^2(x) \right) - \sigma(x)\pi'(x) + \sigma'(x)\pi(x) \right] = 0$$

which we immediately integrate into

$$\omega_1 \left[\pi^2(x) + \sigma^2(x) - m^2 \right] = \sigma(x)\pi'(x) - \sigma'(x)\pi(x). \quad (4.7)$$

Here we have used the boundary conditions (2.2) to determine the integration constant. The next simplest equation is obtained by setting to zero the part of the ω^3 coefficient in (4.6) that is odd in σ and π , and so on.

Following our general discussion we solve the system of coupled equations (3.6) and (4.7), which leads to

$$\frac{d}{dx} \left[\frac{1}{\sigma(x) - m} \right] - \frac{2\omega_1 \tan \frac{\theta}{2}}{\sigma(x) - m} = \frac{2\omega_1}{m \sin \theta}. \quad (4.8)$$

Solving (4.8) we find

$$\begin{aligned} \sigma(x) &= m - \frac{m \sin \theta \tan \frac{\theta}{2}}{1 + \exp \left[2\omega_1 \tan \frac{\theta}{2} \cdot (x - x_0) \right]} \\ \pi(x) &= \frac{m \sin \theta}{1 + \exp \left[2\omega_1 \tan \frac{\theta}{2} \cdot (x - x_0) \right]} \end{aligned} \quad (4.9)$$

where we have chosen the integration constant (parametrised by x_0) such that $\sigma(x)$ and $\pi(x)$ would be free of poles. Note that the boundary conditions at $x \rightarrow +\infty$ require

$$\omega_1 \tan \frac{\theta}{2} < 0. \quad (4.10)$$

Substituting the expressions (4.9) into (4.4) one finds that the resulting $B(x)$ is indeed a solution of the corresponding Gel'fand-Dikii equation (3.1), verifying the consistency of our solution. Our results (4.9) for $\sigma(x)$ and $\pi(x)$ agree with those of

[16]. They have the profile of an extended object, a lump or a chiral “bag”, of size of the order $\cot\frac{\theta}{2}/\omega_1$ centred around an arbitrary point x_0 . Note that the profiles in (4.9) satisfy

$$\rho^2(x) = \sigma^2(x) + \pi^2(x) = m^2 - m^2 \sin^2(\theta/2) \operatorname{sech}^2 \left[\omega_1 \tan \frac{\theta}{2} \cdot (x - x_0) \right]. \quad (4.11)$$

Thus, as expected by construction, this configuration interpolates between two different vacua at $x = \pm\infty$. As x increases from $-\infty$, the vacuum configuration becomes distorted. The distortion reaches its maximum at the location of the “bag”, where $m^2 - \rho^2(x_0) = m^2 \sin^2(\theta/2)$ and then relaxes back into the other vacuum state at $x = \infty$. The arbitrariness of x_0 is, of course, a manifestation of translational invariance.

4.2 Two Bound States

In this case (3.3) becomes

$$B(x) = \frac{B_3(x)\omega^3 + B_2(x)\omega^2 + B_1(x)\omega + B_0(x)}{(\omega - \omega_1)(\omega - \omega_2)\sqrt{m^2 - \omega^2}} \quad (4.12)$$

where the bound state energies are ω_1 and ω_2 . (Obviously, $B(x)$ in this subsection should not be confused with its counterpart in the previous subsection.) In this case the polynomial (3.4) is of degree seven in ω . Following the procedure outlined in Section 3 we find after imposing the boundary conditions (2.2) that

$$\begin{aligned} B(x) = & \frac{\omega + \pi(x)}{2\sqrt{m^2 - \omega^2}} + \\ & \frac{[\sigma^2(x) + \pi^2(x) - \sigma'(x) - m^2][\pi(x) + \omega - \omega_1 - \omega_2]}{4(\omega - \omega_1)(\omega - \omega_2)\sqrt{m^2 - \omega^2}} \\ & - \frac{\pi''(x) - 2\sigma(x)\pi'(x)}{8(\omega - \omega_1)(\omega - \omega_2)\sqrt{m^2 - \omega^2}}. \end{aligned} \quad (4.13)$$

Then, from (2.11) we find that

$$\begin{aligned} C(x) = & -\frac{\omega - \pi(x)}{2\sqrt{m^2 - \omega^2}} - \\ & \frac{[\sigma^2(x) + \pi^2(x) + \sigma'(x) - m^2][-\pi(x) + \omega - \omega_1 - \omega_2]}{4(\omega - \omega_1)(\omega - \omega_2)\sqrt{m^2 - \omega^2}} \\ & - \frac{\pi''(x) + 2\sigma(x)\pi'(x)}{8(\omega - \omega_1)(\omega - \omega_2)\sqrt{m^2 - \omega^2}}. \end{aligned} \quad (4.14)$$

Note that if we set $\omega_1 + \omega_2 = 0$ and $\pi(x) = 0$ the resolvents (4.13) and (4.14), and therefore the whole spectrum, become invariant under $\omega \rightarrow -\omega$, and we obtain the equation appropriate to the Gross-Neveu model.

Setting to zero the coefficients of ω^7 through ω^4 in the degree seven polynomial (3.4), we are left with a cubic polynomial in ω which we do not write down explicitly. This polynomial must vanish identically, producing eight coupled differential

equations in $\sigma(x)$ and $\pi(x)$ as we discussed above. The simplest equation of these is obtained by setting to zero the part of the ω^3 coefficient in that polynomial which unlike the previous case, is now odd in σ and π

$$2\partial_x \left\{ 4(\omega_1 + \omega_2) [\pi^2(x) + \sigma^2(x) - m^2] \pi(x) + 6[\pi^2(x) + \sigma^2(x)] \sigma'(x) \right. \\ \left. + 2(2\omega_1\omega_2 - m^2) \sigma'(x) - 2(\omega_1 + \omega_2) \pi''(x) - \sigma'''(x) \right\} = 0. \quad (4.15)$$

As in the previous case, this is a complete derivative which we readily integrate into

$$4(\omega_1 + \omega_2) [\pi^2(x) + \sigma^2(x) - m^2] \pi(x) + 6[\pi^2(x) + \sigma^2(x)] \sigma'(x) \\ + 2(2\omega_1\omega_2 - m^2) \sigma'(x) - 2(\omega_1 + \omega_2) \pi''(x) - \sigma'''(x) = 0. \quad (4.16)$$

Here we have used the boundary conditions (2.2) to determine the integration constant. Note that (4.16) is of third order in derivatives and cubic, whereas its single bound state counterpart (4.7) is only first order in derivatives and quadratic.

The next simplest equation is obtained by setting to zero the part of the ω^3 coefficient in the cubic polynomial that is even in σ and π ,

$$2\partial_x \left\{ 2(m^2 - 2\omega_1\omega_2) [\pi^2(x) + \sigma^2(x)] - 3[\pi^2(x) + \sigma^2(x)]^2 + 4(\omega_1 + \omega_2) \right. \\ \left. \cdot [\sigma(x)\pi'(x) - \sigma'(x)\pi(x)] \right\} + 4[\pi(x)\pi'''(x) + \sigma(x)\sigma'''(x)] = 0. \quad (4.17)$$

and so on.

Following our general discussion we have to solve the system of coupled equations (3.6) and (4.16) which is equivalent to

$$2\lambda(\omega_1 + \omega_2) [4m y^2 + 2(1 + \lambda^2)y^3 - y''] \\ + \partial_x \{ 4(m^2 + \omega_1\omega_2)y + 6m y^2 + 2(\lambda^2 + 1)y^3 - y'' \} = 0 \quad (4.18)$$

where $\lambda = -\cot(\theta/2)$ and $y(x) = \sigma(x) - m$. We have not succeeded in solving this non-linear ordinary differential equation in closed form.

5 The Saddle Point Conditions

Derivation of the explicit expressions of $\sigma(x)$ and $\pi(x)$ does not involve the saddle point equations (1.7). Rather, it tells us independently of the large N approximation that $\sigma(x)$ and $\pi(x)$ must have the form given in (4.9) in order for the associated Dirac operator to be reflectionless and to have a single bound state at a prescribed energy ω_1 in addition to scattering states. Thus, for the solution (4.9) we have yet to determine the values of ω_1 and θ allowed by the saddle point condition. More generally, our discussion in Section III will lead us to the $\sigma(x)$ and $\pi(x)$ configurations which correspond to reflectionless Dirac operators with a prescribed number of bound states at some prescribed energies $\omega_1, \omega_2, \dots$ in addition to scattering states. As emphasized earlier, this result is independent of the large N limit. The allowed values of $\theta, \omega_1, \omega_2, \dots$ must then be determined by the saddle point condition (1.7). It is this dynamical feature that we can analyse only in the large N limit.

For static background fields the general saddle point condition (1.7) assume the simpler form

$$\begin{aligned}\sigma(x) + Ng^2 \int \frac{d\omega}{2\pi} [A(x) + D(x)] &= 0 \\ \pi(x) + iNg^2 \int \frac{d\omega}{2\pi} [B(x) + C(x)] &= 0.\end{aligned}\tag{5.19}$$

In Subsection 5.1 we impose this condition on the explicit single bound state background we found in the previous section and calculate the mass of such “bags”. The two bound states case is discussed in Subsection 5.2.

5.1 A single bound state

Substituting (4.4), (4.5) into the saddle point equations (5.19) we obtain¹⁵

¹⁵In the following formula we omit explicit x dependence of the fields. The number π also appears in the formula, but only in the combination $\frac{d\omega}{2\pi}$. Therefore there is no danger of confusing the field $\pi(x)$ and the number π .

$$\begin{aligned}
& \frac{\sigma}{Ng^2} + i \int_{-\Lambda}^{\Lambda} \frac{d\omega}{2\pi} \frac{1}{4\sqrt{m^2 - \omega^2} (\omega - \omega_1) (\omega^2 - \pi^2)} \left\{ 4\sigma\omega^3 + 2(\pi' - 2\omega_1\sigma)\omega^2 \right. \\
& \left. + 2 \left[\sigma(\sigma^2 - \pi^2 - m^2) - \omega_1\pi' - \frac{1}{2}\sigma'' \right] \omega - 2\pi^2(\pi' - 2\omega_1\sigma) \right\} = 0 \\
& \frac{\pi}{Ng^2} + i \int_{-\Lambda}^{\Lambda} \frac{d\omega}{2\pi} \frac{2\pi\omega - 2\omega_1\pi - \sigma'}{2\sqrt{m^2 - \omega^2} (\omega - \omega_1)} = 0.
\end{aligned} \tag{5.20}$$

These equations are dispersion relations among the various x dependent parts and ω_1 . Clearly, both dispersion integrals in (5.20) are logarithmically divergent in Λ , but subtracting each of the integrals once we can get rid of these divergences. The required subtractions are actually already built in in (5.20). In order to see this consider the (bare) gap equation (1.8) in Minkowski space. This equation is equivalent to the (logarithmically divergent) dispersion relation¹⁶

$$\frac{i}{Ng^2} = \int_{-\Lambda}^{\Lambda} \frac{d\omega}{2\pi} \frac{1}{\sqrt{m^2 - \omega^2 + i\epsilon}}. \tag{5.21}$$

If we now replace each of the $\frac{1}{Ng^2}$ coefficients in (5.20) by the integral on the right hand side of (5.21) [7], the divergent parts of each pair of integrals cancel and the equations (5.20) become

$$\begin{aligned}
\int_{\mathcal{C}} \frac{d\omega}{2\pi} \frac{\pi' + \frac{\omega}{\omega^2 - \pi^2} F(\sigma, \pi)}{\sqrt{m^2 - \omega^2} (\omega - \omega_1)} &= 0 \\
\int_{\mathcal{C}} \frac{d\omega}{2\pi} \frac{\sigma'}{\sqrt{m^2 - \omega^2} (\omega - \omega_1)} &= 0
\end{aligned} \tag{5.22}$$

where

$$F(\sigma, \pi) = \sigma(\sigma^2 + \pi^2 - m^2) - \omega_1\pi' - \frac{1}{2}\sigma'' \tag{5.23}$$

and $\mathcal{C}$ is the contour in the complex ω plane depicted in Fig.(1).

¹⁶To see this equivalence simply perform (contour) integration over spatial momentum first.

Fig. 1: The contour $\mathcal{C}$ in the complex ω plane in Eq. (5.22). The continuum states appear as the two cuts along the real axis with branch points at $\pm m$ (wiggly lines), and the bound state is the pole at ω .

The expression (5.23) is the residue of the x dependent poles at $\omega = \pm\pi(x)$ in the first equation in (5.22). The quantisation condition (5.22) on ω_1 cannot be x dependent. Therefore (5.23) must vanish as a consistency requirement. Substituting¹⁷ (4.9) in (5.23) we find that

$$F(x) = \frac{m \tan^2 \frac{\theta}{2}}{2} \operatorname{sech}^3 \left[\omega_1 x \tan \frac{\theta}{2} \right] \left[\cos \theta e^{-\omega_1 x \tan \frac{\theta}{2}} + e^{\omega_1 x \tan \frac{\theta}{2}} \right] \left(\omega_1^2 - m^2 \cos^2 \frac{\theta}{2} \right).$$

Thus, $F(\sigma, \pi)$ vanishes for the configurations (4.9) provided

$$\omega_1^2 = m^2 \cos^2 \left(\frac{\theta}{2} \right) \quad (5.24)$$

which sets an interesting relation between the bound state energy and the chiral alignment angle of the vacuum at $x \rightarrow +\infty$. This relation actually leaves θ the only free parameter in the problem with respect to which we have to extremise the action. The condition (4.10) then picks out one branch of (5.24).

We still have to determine ω_1 and θ separately. Now the saddle point condition simply boils down to the single equation

$$I(\omega_1) = \int_{\mathcal{C}} \frac{d\omega}{2\pi} \frac{1}{\sqrt{m^2 - \omega^2} (\omega - \omega_1)} = 0. \quad (5.25)$$

¹⁷Here we have set $x_0 = 0$ for simplicity.

The contour integral in (5.25) is most conveniently calculated by deforming the contour $\mathcal{C}$ into the contour $\mathcal{C}'$ shown in Fig.(2). The “hairpin” wing of $\mathcal{C}'$ picks up the contribution of the filled Fermi sea, and the little circle around the simple pole at $\omega = \omega_1$ is the contribution of fermions populating the bound state of the “bag”.

Fig. 2: The deformed integration contour $\mathcal{C}'$ leading to Eq. (5.26).

Assuming that the “bag” traps n fermions in that state, and recalling that each state in the Fermi sea continuum accomodates N fermions, we see that (5.25) becomes

$$I(\omega_1) = \frac{iN}{\sqrt{m^2 - \omega_1^2}} \left[\frac{2}{\pi} \arctan \sqrt{\frac{m + \omega_1}{m - \omega_1}} + \frac{n}{N} - 1 \right] = 0 \quad (5.26)$$

The solution of this equation yields the quantisation condition

$$\omega_1 = m \cos \left(\frac{n\pi}{N} \right) \quad (5.27)$$

in agreement with [16].

It follows from (4.9), (4.10) and (5.24) that

$$\theta = -\frac{2\pi n}{N}, \quad (5.28)$$

that is, the relative chiral rotation of the vacua at $\pm\infty$ is proportional to the number of fermions trapped in the “bag”. Our result (5.28) is consistent with the well known result that the fermion number current in a soliton background can be determined in some cases by topological considerations[24]. Note from (5.28), that in the large

N limit, θ (and therefore ω_1) take on non-trivial values only when the number of the trapped fermions scales as a finite fraction of N .

As we already mentioned in the introduction, stability of “bags” formed in the NJL model are not stable because of topology. They are stabilised by releasing binding energy of the fermions trapped in them. To see this more explicitly, we calculate now the mass of the “bag” corresponding to (4.9), (5.27) and (5.28). The effective action (1.6) for background fields (4.9) is an ordinary function of the chiral angle θ ¹⁸. Let us denote this action per unit time by $S(\theta)/T$. Then, from (2.9) and (5.21) we find

$$\begin{aligned} \frac{1}{T} \frac{\partial S}{\partial \theta} = & \int \frac{dx d\omega}{2\pi} \left\{ \left[\frac{i\sigma(x)}{\sqrt{m^2 - \omega^2}} - (A + D) \right] \frac{\partial \sigma(x)}{\partial \theta} \right. \\ & \left. + i \left[\frac{\pi(x)}{\sqrt{m^2 - \omega^2}} - (B + C) \right] \frac{\partial \pi(x)}{\partial \theta} \right\}. \end{aligned} \quad (5.29)$$

Then as in our analysis of the saddle point condition (which is simply the condition for $\frac{\partial S}{\partial \theta} = 0$) we use (4.4), (4.5), (2.10) and the fact that (5.23) vanishes to find

$$\frac{1}{T} \frac{\partial S}{\partial \theta} = i \int \frac{dx d\omega}{2\pi} \frac{\partial_x \sigma(x) \partial_\theta \pi(x) - \partial_x \pi(x) \partial_\theta \sigma(x)}{2(\omega - \omega_1) \sqrt{m^2 - \omega^2}}.$$

Then, (3.6) leads to the factorised expression

$$\frac{1}{T} \frac{\partial S}{\partial \theta} = \frac{i}{4 \sin^2 \frac{\theta}{2}} \int_{-\infty}^{\infty} dx (\sigma - m) \sigma' \int_{\mathcal{C}'} \frac{d\omega}{2\pi} \frac{1}{(\omega - \omega_1) \sqrt{m^2 - \omega^2}} \quad (5.30)$$

where $\mathcal{C}'$ is the contour in Fig.(2). The space integral is immediate and is essentially fixed by the boundary conditions (2.2). The spectral integral is given by the left hand side of (5.26), but with a generic ω_1 given by $\omega_1 = m \cos(\frac{\theta}{2})$. Here we have chosen the particular branch of (5.24) that contains all the extremal values of ω_1 . Putting everything together we finally arrive at

$$\frac{1}{NT} \frac{\partial S}{\partial \theta} = \frac{m}{2} \left(\frac{n}{N} + \frac{\theta}{2\pi} \right) \sin \frac{\theta}{2}. \quad (5.31)$$

¹⁸Recall that ω_1 is a function of θ and not a free parameter.

The zeros of (5.31) are simply the zeros of (5.26), as these two equations are one and the same extremum condition. Integrating (5.31) with respect to θ we finally find

$$\frac{-1}{NTm}S(\theta) = \left(\frac{n}{N} + \frac{\theta}{2\pi}\right)\cos\frac{\theta}{2} - \frac{1}{\pi}\sin\frac{\theta}{2}. \quad (5.32)$$

Note that (5.32) is not manifestly periodic in θ because the Pauli exclusion principle limits θ to be between 0 and 2π .

The mass of a “bag” containing n fermions in a single bound state is given by $-S/T$ evaluated at the appropriate chiral angle (5.28). We thus find that this mass is simply

$$M_n = \frac{Nm}{\pi}\sin\frac{\pi n}{N} \quad (5.33)$$

in accordance with [16, 20]. These “bags” are stable because

$$\sin\frac{\pi(n_1 + n_2)}{N} < \sin\frac{\pi n_1}{N} + \sin\frac{\pi n_2}{N} \quad (5.34)$$

for n_1, n_2 less than N , such that a “bag” with $n_1 + n_2$ fermions cannot decay into two “bags” each containing a lower number of fermions.

Entrapment of a small number of fermions cannot distort the homogeneous vacuum considerably, so we expect that M_n will be roughly the mass of n free massive fermions for $n \ll N$. As a matter of fact we used this expectation to fix the integration constant in (5.33). For $n \ll N$ we have $M_n \sim nm[1 - \frac{1}{6}\left(\frac{\pi n}{N}\right)^2 + \dots]$, so the binding energy released

$$B_n \sim \frac{nm}{6}\left(\frac{\pi n}{N}\right)^2 + \dots \quad (5.35)$$

is indeed very small. However, as the number of fermions trapped in the “bag” approaches N , M_n vanishes and the fermions release practically all their rest mass Nm as binding energy, to achieve maximum stability[17]. In a weakly coupled field theory containing solitons, the mass of these extended objects is a measure of $\frac{1}{g^2}$, the inverse square of the coupling constant. Here we have $\frac{1}{g^2} = N$. It is amusing to speculate that these maximally stable massless solitons may teach us something about the strong coupling regime of the NJL model.

Note from (5.28), that the soliton twists all the way around as the number of fermions approaches N . In this case $\omega_1 \rightarrow -m$, and the pole the resolvent has at $\omega = \omega_1$ pinches the branchpoint $\omega = -m$ at the edge of the filled Dirac sea. One may wonder whether this enhanced singularity is a mathematical artifact, as the bound state simply tries to plunge into the filled Dirac sea. But this is clearly not the case. Indeed, ω_1 is occupied by N fermions (in a flavor singlet). Their common spinor wave function must still be part of the discrete spectrum of the Dirac operator, because the highest lying state of the sea at $\omega = -m$ is already occupied by a flavor singlet made of N fermions, sharing a continuum spinor wave function, and therefore Pauli's exclusion principle protects the bound state from “dissolving” into the sea.

5.2 Two bound states

We concluded Subsection 4.2 short of an explicit solution of (4.18), namely, short of an explicit expression for the two bound state background fields $\sigma(x)$ and $\pi(x)$. In the following we make the eminently reasonable assumption that such a background exists, and pursue our analysis of its saddle point condition as far as we can without having its explicit form in hand.

As in the previous subsection, we substitute (4.13) and (4.14) into the saddle point equations (5.19). We then make use of (5.21) to eliminate the ultraviolet logarithmic divergences and to write the saddle point conditions as

$$\begin{aligned}
& \int_{\mathcal{C}''} \frac{d\omega}{2\pi} \left[\frac{i\sigma(x)}{\sqrt{m^2 - \omega^2}} - (A + D) \right] = \\
& i \int_{\mathcal{C}''} \frac{d\omega}{2\pi} \frac{K + \omega \frac{L}{\omega^2 - \pi^2(x)}}{2\sqrt{m^2 - m^2}(\omega - \omega_1)(\omega - \omega_2)} \\
& \quad \text{rmand} \\
& \int_{\mathcal{C}''} \frac{d\omega}{2\pi} \left[\frac{\pi(x)}{\sqrt{m^2 - \omega^2}} - (B + C) \right] = \\
& \int_{\mathcal{C}''} \frac{d\omega}{2\pi} \frac{M + \omega\sigma'(x)}{2\sqrt{m^2 - m^2}(\omega - \omega_1)(\omega - \omega_2)} \tag{5.36}
\end{aligned}$$

where $\mathcal{C}''$ is a contour similar to the contour $\mathcal{C}'$ in Fig.(2) that encircles the additional pole at ω_2 as well, and $K(x)$, $L(x)$ and $M(x)$ are given by

$$\begin{aligned}
K(\sigma, \pi) &= -\sigma(\sigma^2 + \pi^2 - m^2) + (\omega_1 + \omega_2)\pi' + \frac{1}{2}\sigma'' \\
L(\sigma, \pi) &= (\omega_1 + \omega_2) \left[\sigma(\sigma^2 + \pi^2 - m^2) - \frac{1}{2}\sigma'' \right] - \left(\frac{\sigma^2 + \pi^2 - m^2}{2} + \omega_1\omega_2 + \sigma^2 \right) \pi' \\
&\quad + \frac{\pi'''}{4} \\
&\text{and} \\
M(\sigma, \pi) &= -\pi(\sigma^2 + \pi^2 - m^2) - (\omega_1 + \omega_2)\pi' + \frac{1}{2}\pi''.
\end{aligned} \tag{5.37}$$

Note that $K(\sigma, \pi)$ differs from $-F(\sigma, \pi)$ in (5.23) only by the additional term $\omega_2\pi'$. The expression $L(\sigma, \pi)$ is the residue of the x dependent poles at $\omega = \pm\pi(x)$ in the first equation in (5.36). The quantisation conditions (5.36) on ω_1 and ω_2 cannot be x dependent. Therefore $L(\sigma, \pi)$ must vanish as a consistency requirement. As we do not have the explicit expressions of $\sigma(x)$ and $\pi(x)$, we assume from now on that L indeed vanishes. This is the only extra assumption we make. Then, assuming that the “bag” traps n_1 fermions in ω_1 and n_2 fermions in ω_2 , (5.36) boils down to the simple conditions

$$I(\omega_1) = I(\omega_2) = 0 \tag{5.38}$$

where $I(\omega)$ is given in (5.26). Therefore,

$$\omega_1 = m \cos \left(\frac{n_1\pi}{N} \right), \quad \omega_2 = m \cos \left(\frac{n_2\pi}{N} \right) \tag{5.39}$$

which are identical in form to single bound state energy levels. From the general considerations of [24] we expect that the chiral angle θ will be proportional to the total number of fermions trapped by the “bag”, so (5.28) must read now

$$\theta = -\frac{2\pi(n_1 + n_2)}{N}. \tag{5.40}$$

The soliton mass is a function of m and of the chiral angle θ . Assuming this function is the same as in the previous case we therefore conjecture that the mass of the two bound state “bag” is simply

$$M_{n_1, n_2} = \frac{Nm}{\pi} \sin \frac{\pi (n_1 + n_2)}{N}. \quad (5.41)$$

As far as mass is concerned, such a “bag” cannot be distinguished from a single bound state “bag” containing the same total number $n_1 + n_2$ of trapped fermions. If our conjecture is true, then such “bags” are stable against decaying into several “bags” with lower numbers of fermions as (5.34) shows.

A Appendix A

In this Appendix we provide precise definitions of the Jost functions b_1 through c_2 in terms of their spatial asymptotic behavior and derive the spatial asymptotic behavior of the static Dirac operator Green's function.

We concentrate for the moment on the first equation in (2.6). The boundary conditions (2.2) lead to the following simple spatial asymptotic behavior

$$[-\partial_x^2 + m^2 - \omega^2] b(x) = 0$$

of the homogeneous part of that equation. Thus, solutions of that homogeneous equation assume the generic asymptotic form

$$b(x, \omega) \sim \begin{cases} M_+ e^{ikx} + N_+ e^{-ikx}, & x \rightarrow +\infty \\ M_- e^{ikx} + N_- e^{-ikx}, & x \rightarrow -\infty \end{cases} \quad (\text{A.1})$$

where

$$k(\omega) = +\sqrt{\omega^2 - m^2}. \quad (\text{A.2})$$

On the real ω axis $k(\omega)$ is real for $|\omega| > m$, which corresponds to scattering states of (2.3). Bound states of (2.3) reside in the domain $|\omega| < m$, where $k(\omega) = +i\sqrt{m^2 - \omega^2} = +i\kappa(\omega)$ is purely imaginary and lies in the upper half plane.

The Jost functions b_1 and b_2 alluded to in Section 2 form a particular pair of linearly independent solution of the homogeneous equation mentioned above, specified by their asymptotic behavior. Let the asymptotic amplitudes of $b_r(x)$, ($r = 1, 2$) in (A.1) be $M_{r\pm}, N_{r\pm}$. The asymptotic form (A.1) of $b_1(x)$ has by definition $M_{1-} = 0$, and that of $b_2(x)$ has $N_{2+} = 0$. One may summarise our definitions of b_1 and b_2 , by saying that b_1 corresponds to a one dimensional scattering situation where the source is at $+\infty$ emitting waves to the left (the term $N_{1+}e^{-ikx}$) and that b_2 corresponds to a one dimensional scattering situation where the source is at $-\infty$ emitting waves to the right (the term $M_{2-}e^{ikx}$). Note also that outside the continuum, $b_1(x)$ decays to the left while $b_2(x)$ decays to the right. With these definitions the Wronskian (2.8)

becomes

$$W_b(+\infty) = -2ik \frac{M_{2+}N_{1+}}{\omega + \pi(+\infty)} = -2ik \frac{M_{2-}N_{1-}}{\omega + \pi(-\infty)} = W_b(-\infty). \quad (\text{A.3})$$

Therefore, it follows from (2.10) and from (2.11) that the entries A, B, C , and D in (2.9) have the asymptotic form

$$\begin{aligned} A(x) &= -\frac{1}{2k} \left\{ [\sigma(x) - ik \operatorname{sgn} x] R(k) e^{2ik|x|} + \sigma(x) \right\} \\ B(x) &= \frac{\omega + \pi(x)}{-2ik} \left[1 + R(k) e^{2ik|x|} \right] \\ C(x) &= \frac{\omega - \pi(x)}{2ik} \left[1 + R(k) e^{2ik|x|} \right] \\ D(x) &= -\frac{1}{2k} \left\{ [\sigma(x) + ik \operatorname{sgn} x] R(k) e^{2ik|x|} + \sigma(x) \right\} \end{aligned} \quad (\text{A.4})$$

as $x \rightarrow \pm\infty$, where

$$R(k) = \frac{M_{1+}}{N_{1+}} = \frac{N_{2-}}{M_{2-}} \quad (\text{A.5})$$

is the reflection coefficient of the Sturm-Liouville operator in the first equation in (2.6). The diagonal resolvent of the Dirac operator is therefore

$$\begin{aligned} \langle x | -iD^{-1} | x \rangle &\xrightarrow{x \rightarrow \pm\infty} \frac{i}{2k} \begin{pmatrix} i\sigma(x) & \omega + \pi(x) \\ -\omega + \pi(x) & i\sigma(x) \end{pmatrix} + \\ &\frac{iR(k) e^{2ik|x|}}{2k} \begin{pmatrix} i\sigma(x) + k \operatorname{sgn} x & \omega + \pi(x) \\ -\omega + \pi(x) & i\sigma(x) - k \operatorname{sgn} x \end{pmatrix}. \end{aligned} \quad (\text{A.6})$$

B Appendix B

Consider the Sturm-Liouville problem

$$-\left[p(x)\psi'(x)\right]' + [V(x) - E\rho(x)]\psi(x) = 0 \quad , \quad -\infty < x < \infty. \quad (\text{B.1})$$

We assume that the “metric” $p(x)$ does not vanish anywhere and that the weight function $\rho(x)$ is positive everywhere. E is a complex number, called the spectral parameter.

As in our discussion in the main text and in the previous appendix, let $\psi_1(x)$ be the Jost function which decays as $x \rightarrow -\infty$ for values of E below the continuum threshold. Similarly, let $\psi_2(x)$ be the Jost function which decays as $x \rightarrow +\infty$. Then, the Green’s function of the operator in (B.1) is

$$G(x, y) = \frac{\theta(x - y) \psi_2(x) \psi_1(y) + \theta(y - x) \psi_2(y) \psi_1(x)}{W} \quad (\text{B.2})$$

where

$$W = p(x) [\psi_2(x) \psi_1'(x) - \psi_1(x) \psi_2'(x)] \quad (\text{B.3})$$

is the (x independent) Wronskian of these two functions. Note that (B.2) decays (at a rate dictated by the Jost functions) as either one of its argument diverges in absolute value, holding the other one finite, as long as E does not hit one of the eigenvalues of the Sturm-Liouville operator.

As in the main text the diagonal resolvent $R(x) = G(x, x)$ is defined as

$$R(x) = \frac{1}{2} \lim_{\epsilon \rightarrow 0} [G(x, x + \epsilon) + G(x + \epsilon, x)] = \frac{\psi_1(x) \psi_2(x)}{W}. \quad (\text{B.4})$$

We then use (B.3) and (B.4) to show that

$$\frac{\psi_1'}{\psi_1} = \frac{pR' + 1}{2pR} \quad , \quad \frac{\psi_2'}{\psi_2} = \frac{pR' - 1}{2pR}. \quad (\text{B.5})$$

Finally, using (B.1) and (B.5) we find

$$(pR')' = 2(V - E\rho)R + \frac{(pR')^2 - 1}{2pR} \quad (\text{B.6})$$

and

$$[p(pR')']' = [2p(V - E\rho)R]' + 2p(V - E\rho)R'. \quad (\text{B.7})$$

Note that the non-linearity of (B.6) in R has disappeared after one more differentiation with respect to x .

Multiplying (B.6) through by $2R$ we find

$$-2pR(pR')' + (pR')^2 + 4pR^2(V - \rho E) = 1 \quad (\text{B.8})$$

which is the Gel'fand-Dikii equation [6]. Eq. (B.7) is the linear form of the Gel'fand-Dikii equation we use in the text (Eq. (3.1)).

The quantities corresponding to the discussion of the Dirac operator in the text are

$$\begin{aligned} p(x) &= \rho(x) = \frac{1}{\omega + \pi(x)} \quad , \quad E = \omega^2 \\ \text{and} \\ V(x) &= \frac{1}{\omega + \pi(x)} \cdot \left[\sigma(x)^2 + \pi(x)^2 - \sigma'(x) + \frac{\sigma(x)\pi'(x)}{\omega + \pi(x)} \right]. \end{aligned} \quad (\text{B.9})$$

The Gel'fand-Dikii equation (B.8) then reads

$$\begin{aligned} &-2 \frac{B(x)}{\omega + \pi(x)} \partial_x \left[\frac{\partial_x B(x)}{\omega + \pi(x)} \right] + \left[\frac{\partial_x B(x)}{\omega + \pi(x)} \right]^2 + \\ &\left[\frac{2B(x)}{\omega + \pi(x)} \right]^2 \left[\sigma(x)^2 + \pi(x)^2 - \sigma'(x) - \omega^2 + \frac{\sigma(x)\pi'(x)}{\omega + \pi(x)} \right] = 1. \end{aligned} \quad (\text{B.10})$$

Strictly speaking, Sturm-Liouville theory requires that $p(x) = \rho(x) = \frac{1}{\omega + \pi(x)} > 0$. Our solution for $\pi(x)$ turns out to be bounded, so all formulae are valid a posteriori for large positive ω . Such a restriction on ω , though mathematically required, is unphysical.

Note however, that because of the relation (2.11), we may view $C(x)$ as a continuation of $B(x)$ to large negative ω .

An important application of the Gel'fand-Dikii identities (B.7), (B.8) is that they generate an asymptotic expansion[6] of R in negative odd powers of $\sqrt{E}$. The explicit ω (and therefore E) dependence of our specific $p(x), \rho(x)$ and $V(x)$ complicates this expansion.

Acknowledgements We would like to thank N. Andrei for valuable discussions, and J. Polchinski for reminding us of [24]. This work was partly supported by the National Science Foundation under Grant No. PHY89-04035.
